# Motivation

Stencil example in Matlab

Parameters:  
1. Number of iterations  
2. Number of columns  
3. Number of rows  
4. Stencil size  
5.25 Polyameric Matrix Size

Computation:  
 $i = 2:2:N-1;$   
for  $j = 1:N-1$   
if  $i < N-1$   
 $T(i,j) = A(i,j) + A(i+1,j) + A(j-1,i) + A(j,i-1)$   
 $A(i,j) = T(i,j)$   
end

Mat with Overlap

Parameters:  
1. Number of iterations  
2. Number of columns  
3. Number of rows  
4. Stencil size  
5.25 Polyameric Matrix Size

Computation:  
 $i = 2:2:N-1;$   
for  $j = 1:N-1$   
if  $i < N-1$   
 $T(i,j) = A(i,j) + A(i+1,j) + A(j-1,i) + A(j,i-1)$   
 $A(i,j) = T(i,j)$   
end

Stencil example in C

Parameters:  
1. Number of iterations  
2. Number of columns  
3. Number of rows  
4. Stencil size  
5.25 Polyameric Matrix Size

Computation:  
 $i = 2:2:N-1;$   
for  $j = 1:N-1$   
if  $i < N-1$   
 $T(i,j) = A(i,j) + A(i+1,j) + A(j-1,i) + A(j,i-1)$   
 $A(i,j) = T(i,j)$   
end

Stencil example in NumPy

Parameters:  
1. Number of iterations  
2. Number of columns  
3. Number of rows  
4. Stencil size  
5.25 Polyameric Matrix Size

Computation:  
 $i = 2:2:N-1;$   
for  $j = 1:N-1$   
if  $i < N-1$   
 $T(i,j) = A(i,j) + A(i+1,j) + A(j-1,i) + A(j,i-1)$   
 $A(i,j) = T(i,j)$   
end

# Stencil example in Matlab

#Parameters

I %Number of iterations

A %Input & Output Matrix

T %Temporary array

SIZE %Symmetric Matrix Size

#Computation

i = 2:SIZE+1;%Center slice vertical

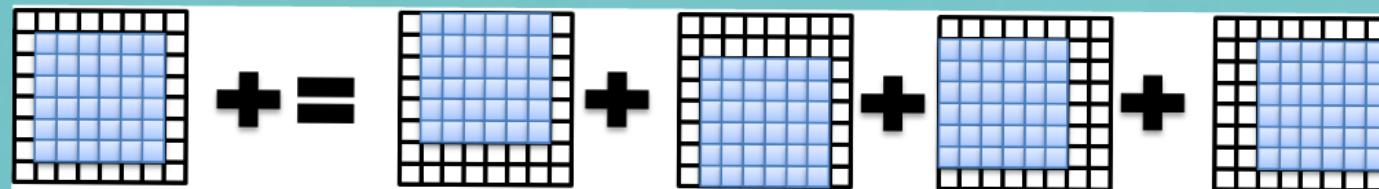

j = 2:SIZE+1;%Center slice horizontal

for n=1:I,

    T(:) = (A(i,j) + A(i+1,j) + A(i-1,j) + A(i,j+1) + A(i,j-1)) / 5.0;

    A(i,j) = T;

end

# Stencil example in C

```
//Parameters
int l;    //Number of iterations
double *A; //Input & Output Matrix
double *T; //Temporary array
int SIZE; //Symmetric Matrix Size

//Computation
int gsize = SIZE+2; //Size + borders.
for(n=0; n<l; n++)
{
    memcpy(T, A, gsize*gsize*sizeof(double));

}
MPI_Barrier(MPI_COMM_WORLD);
```

# Stencil example in NumPy

**#Parameters**

I #Number of iterations  
A #Input & Output Matrix  
T #Temporary array  
**SIZE #Symmetric Matrix Size**

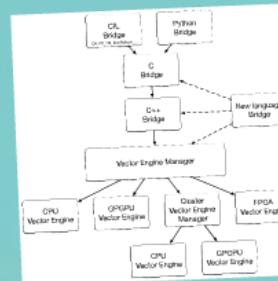

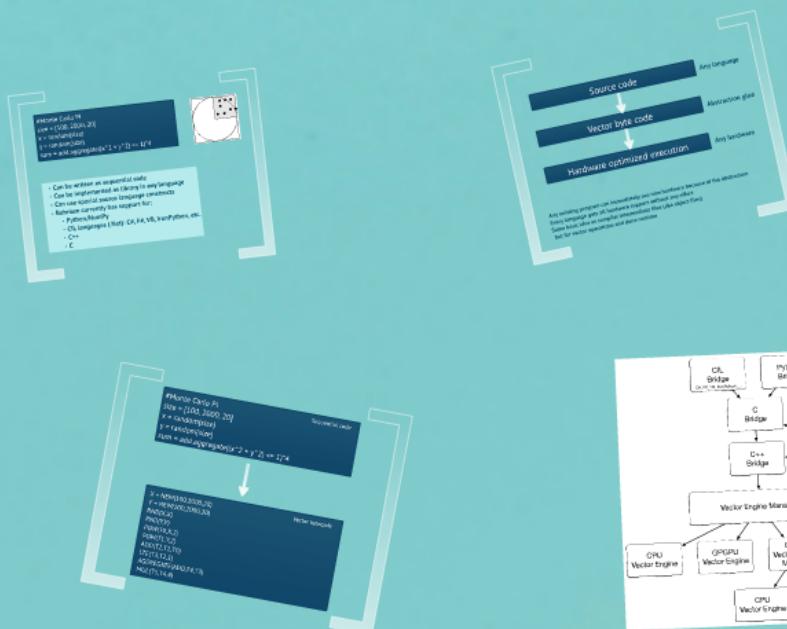

**#Computation**

for i in xrange(I):

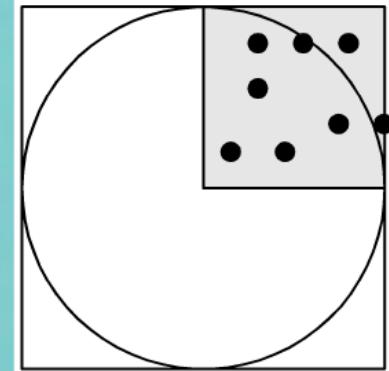

T[:] = (A[1:-1,1:-1] + A[1:-1,:-2] + A[1:-1,2:] + A[:-2,1:-1] \  
+ A[2:,1:-1]) / 5.0

A[1:-1, 1:-1] = T

## How it works

```
#Monte Carlo PI  
size = [100, 2000, 20]  
x = random(size)  
y = random(size)  
sum = add.aggregate((x^2 + y^2) <= 1)*4
```

- Can be written as sequential code
- Can be implemented as library in any language
- Can use special source language constructs
- Bohrium currently has support for:
  - Python/NumPy
  - CIL languages (.Net): C#, F#, VB, IronPython, etc.
  - C++
  - C

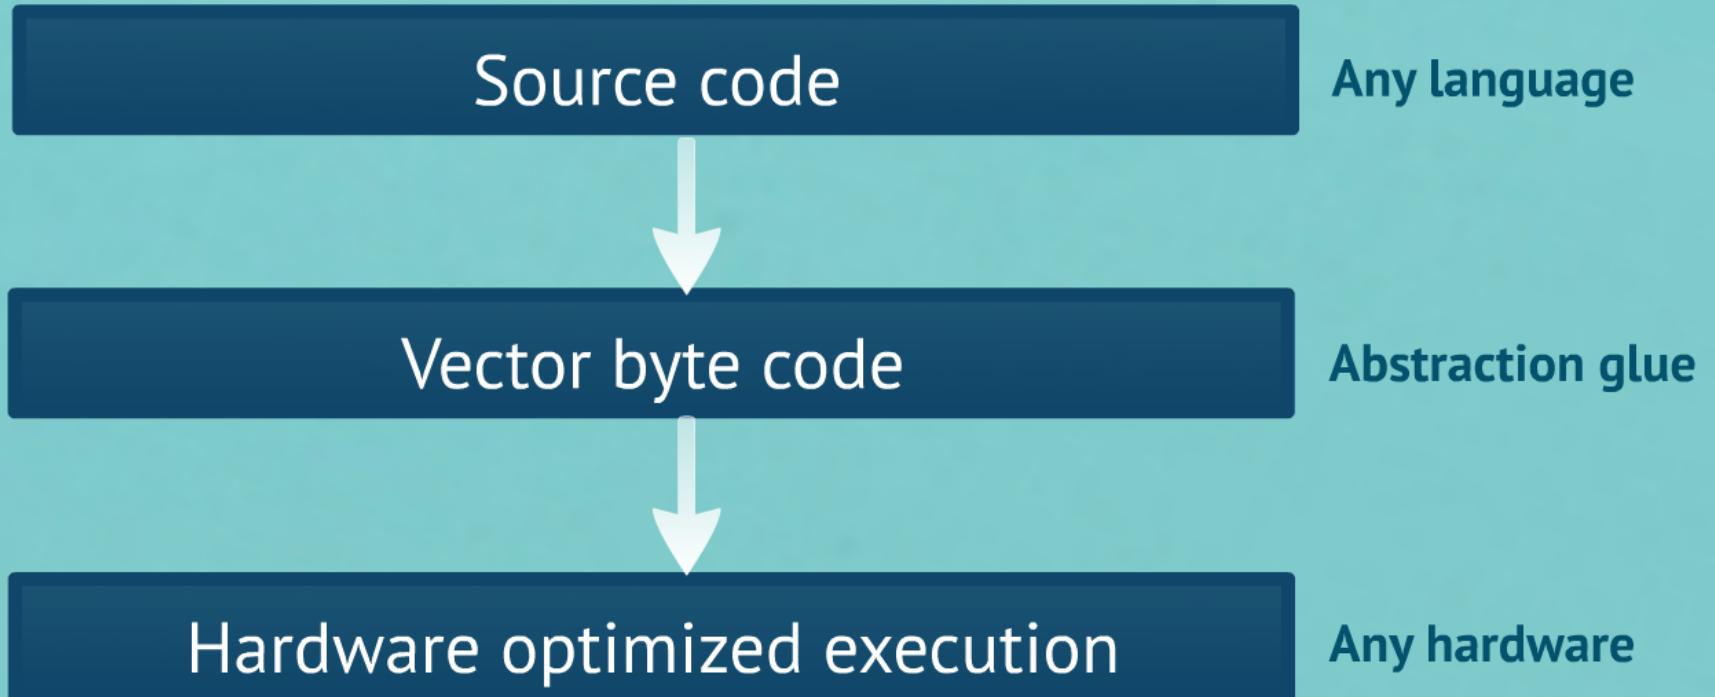

```
#Monte Carlo PI  
size = [100, 2000, 20]  
x = random(size)  
y = random(size)  
sum = add.aggregate((x^2 + y^2) <= 1)*4
```

Sequential code

```
X = NEW(100,2000,20)  
Y = NEW(100,2000,20)  
RND(X,X)  
RND(Y,Y)  
POW(T0,X,2)  
POW(T1,Y,2)  
ADD(T2,T1,T0)  
LTE(T3,T2,1)  
AGGREGATE(ADD,T4,T3)  
MUL(T5,T4,4)
```

Vector bytecode

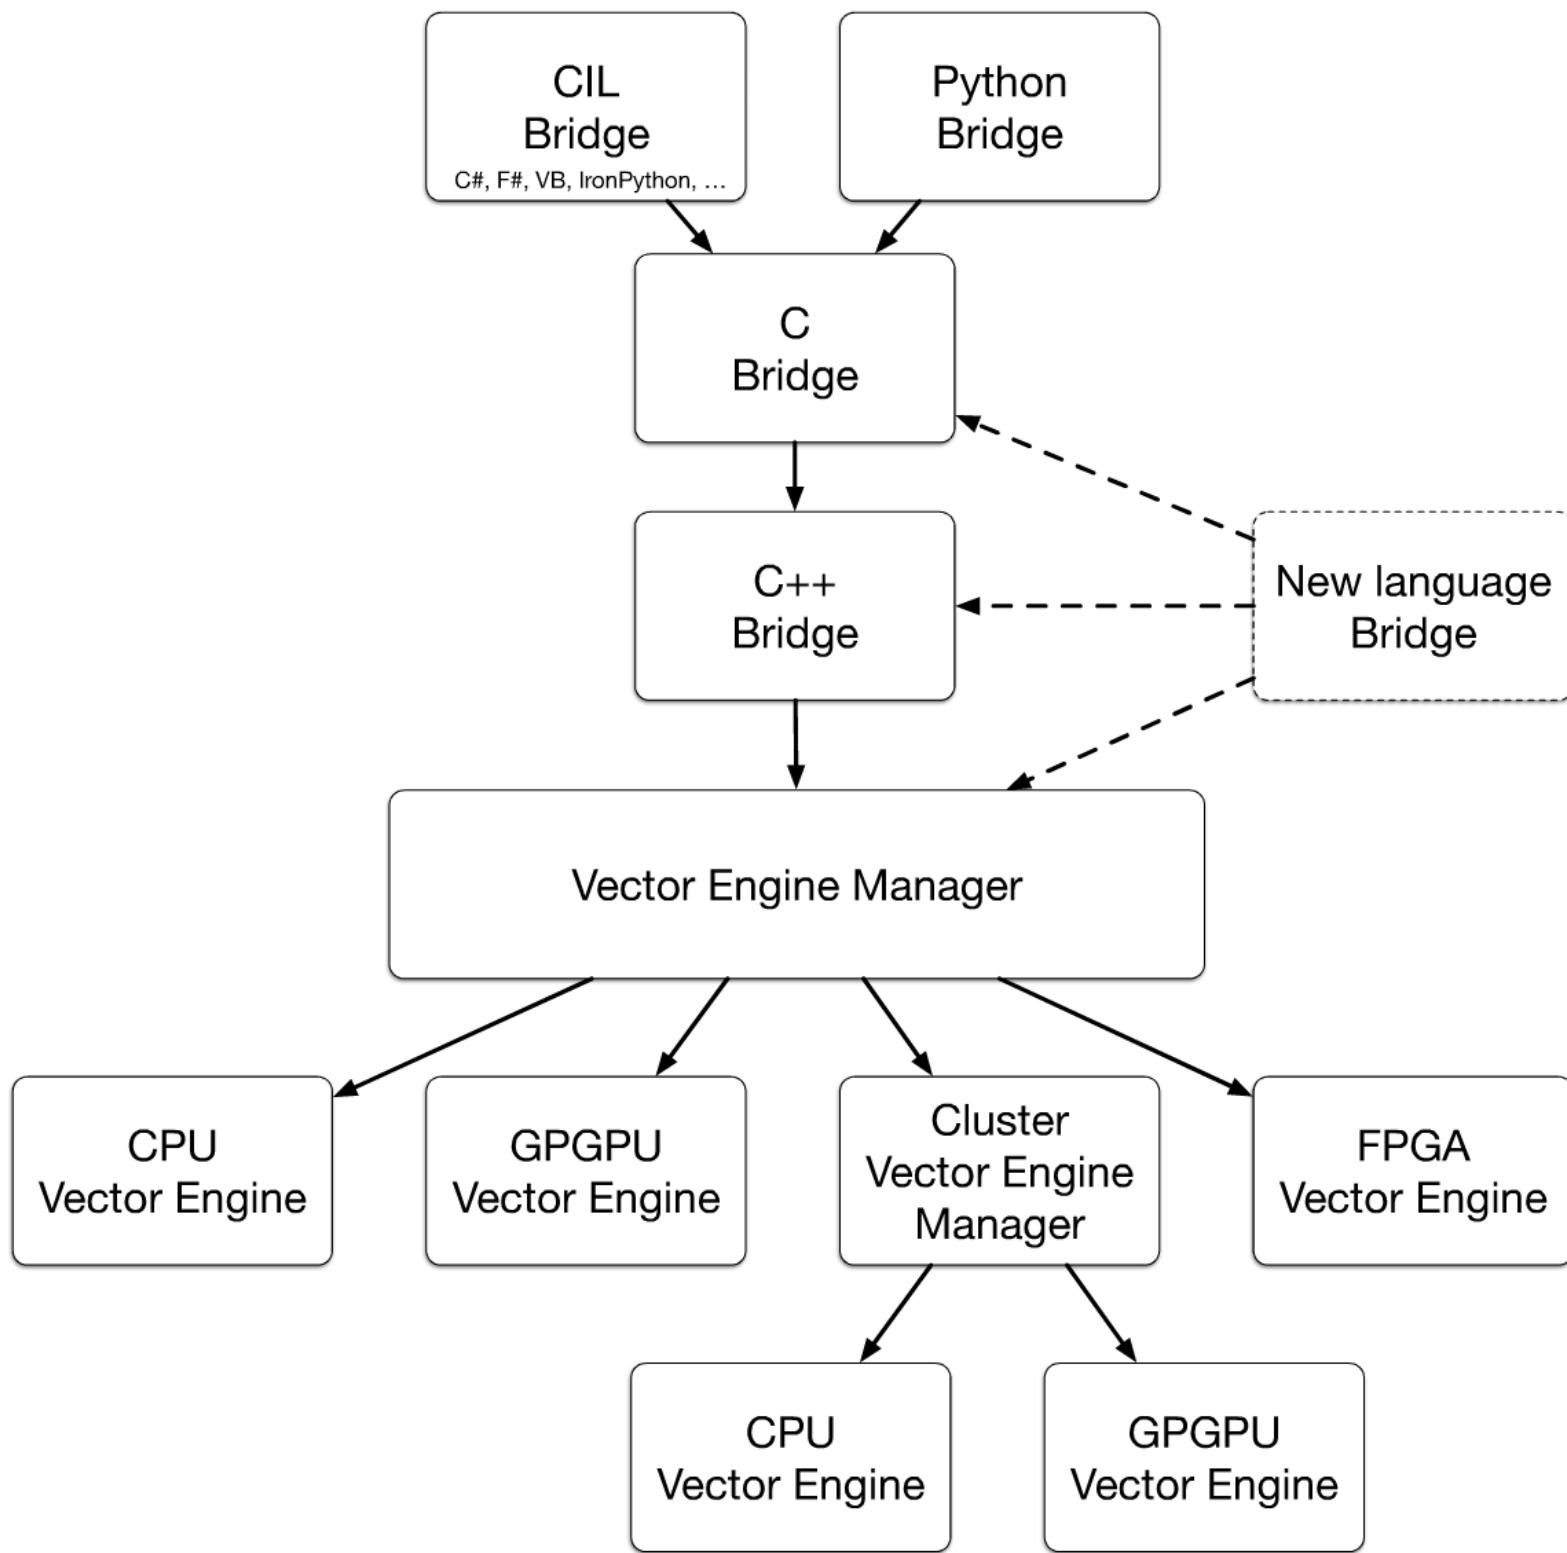

**Any existing program can immediately use new hardware because of the abstraction**

**Every language gets all hardware support without any effort**

**Same basic idea as compiler intermediate files (aka object files)**

**but for vector operations and done runtime**

# Examples

# Shallow water

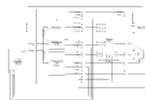

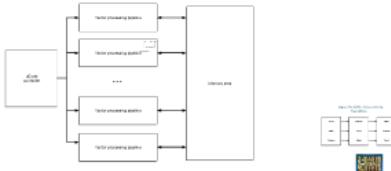

# The FPGA vector engine

## aka: The Bohrium Processing Unit

### Why FPGA ?

**Pro**  
Power efficient  
Stand-alone  
Low cost

**Con**  
Expensive  
Low availability  
Difficult to program

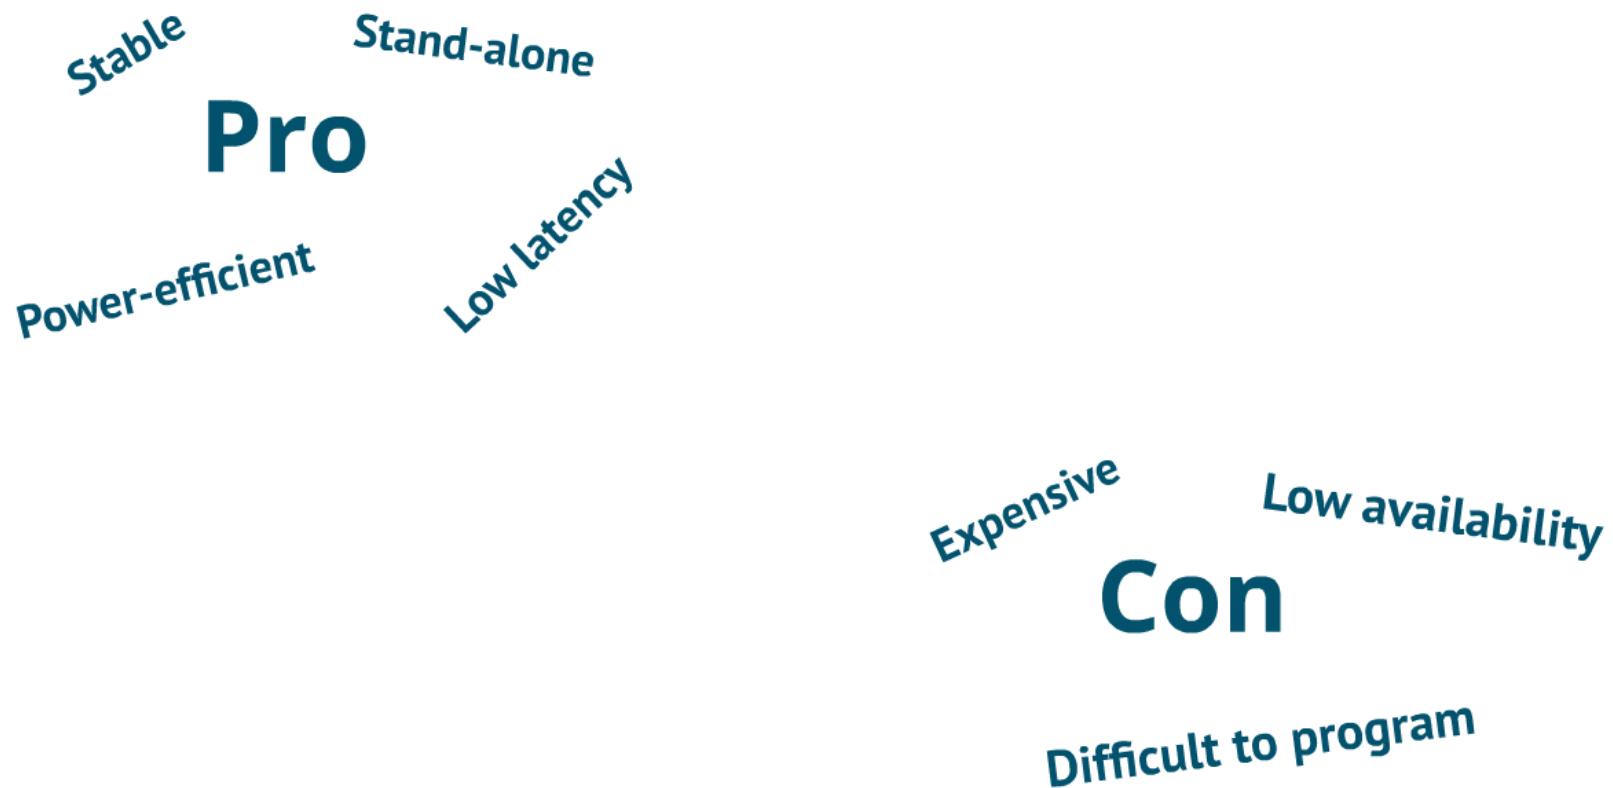

### Micro-code design

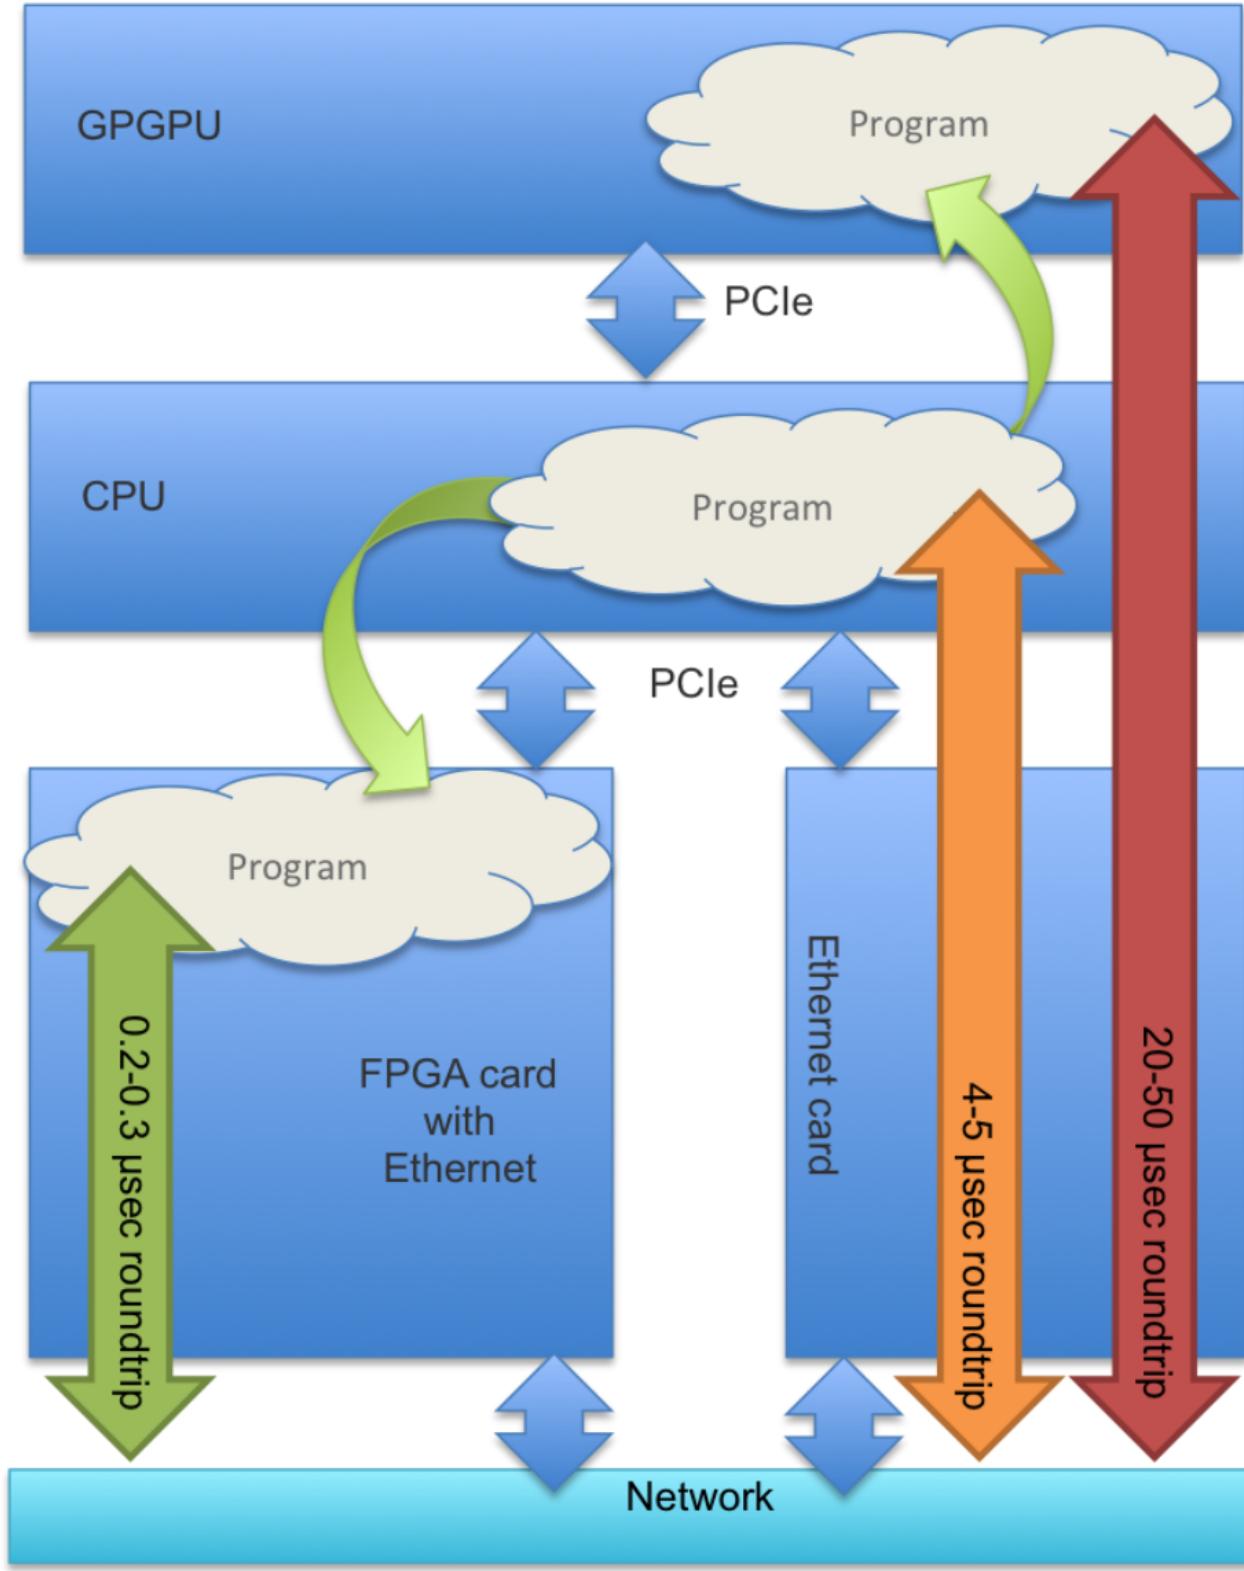

- Each microcode can execute 2 distinct operations:
  - Vector load memory read
  - Vector load memory write
  - Vector result memory
- Each microcode can depend on previous instructions:
  - For reads
  - For writes
  - For results

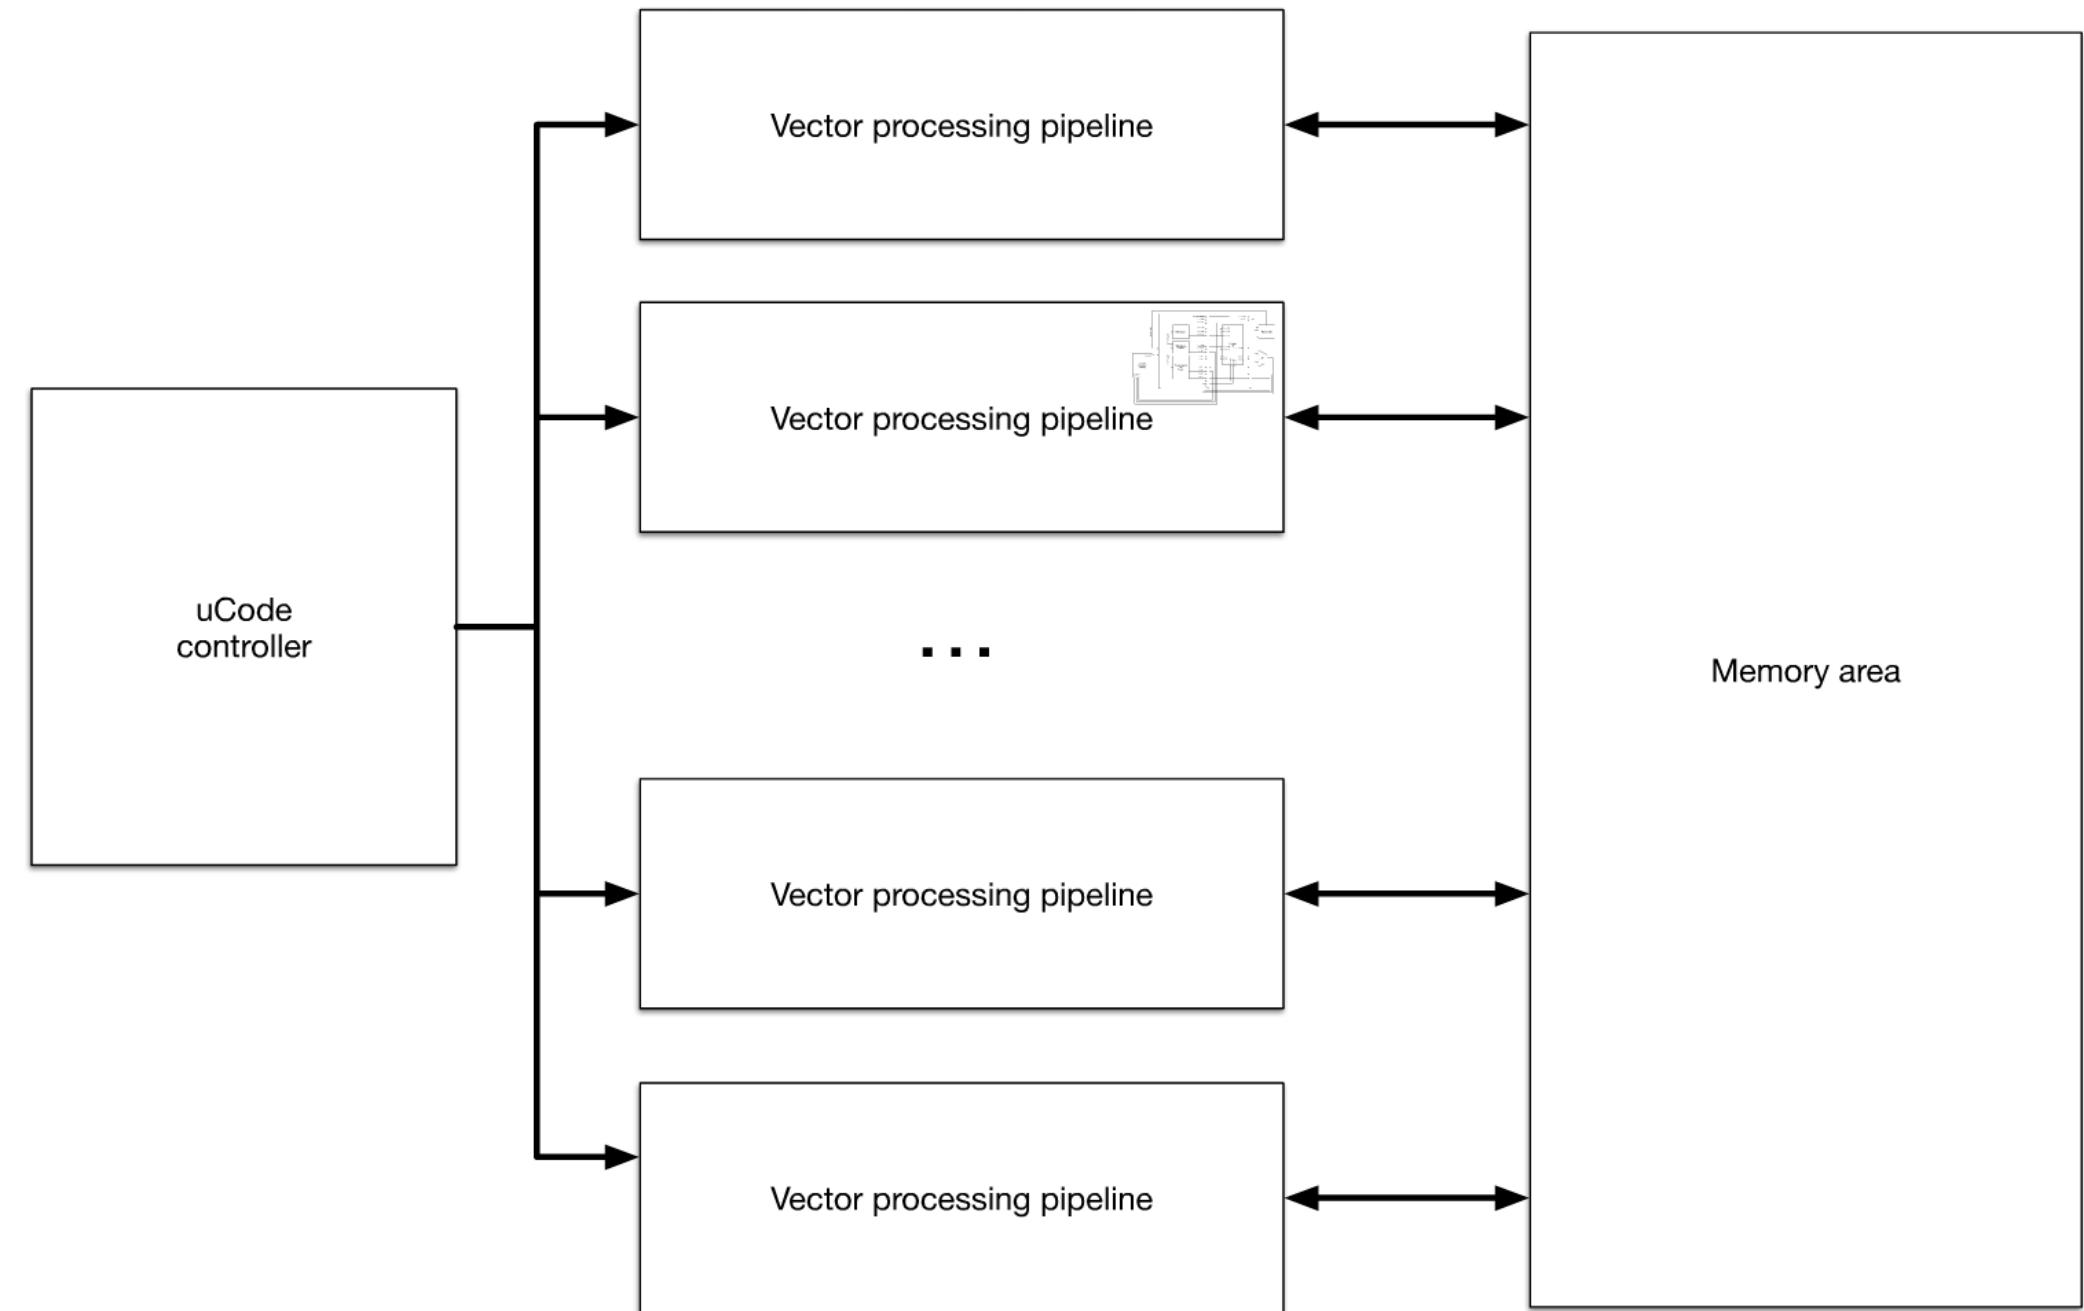

The microcode design places a large burden on the programmer and is not suited for writing concurrent programs.

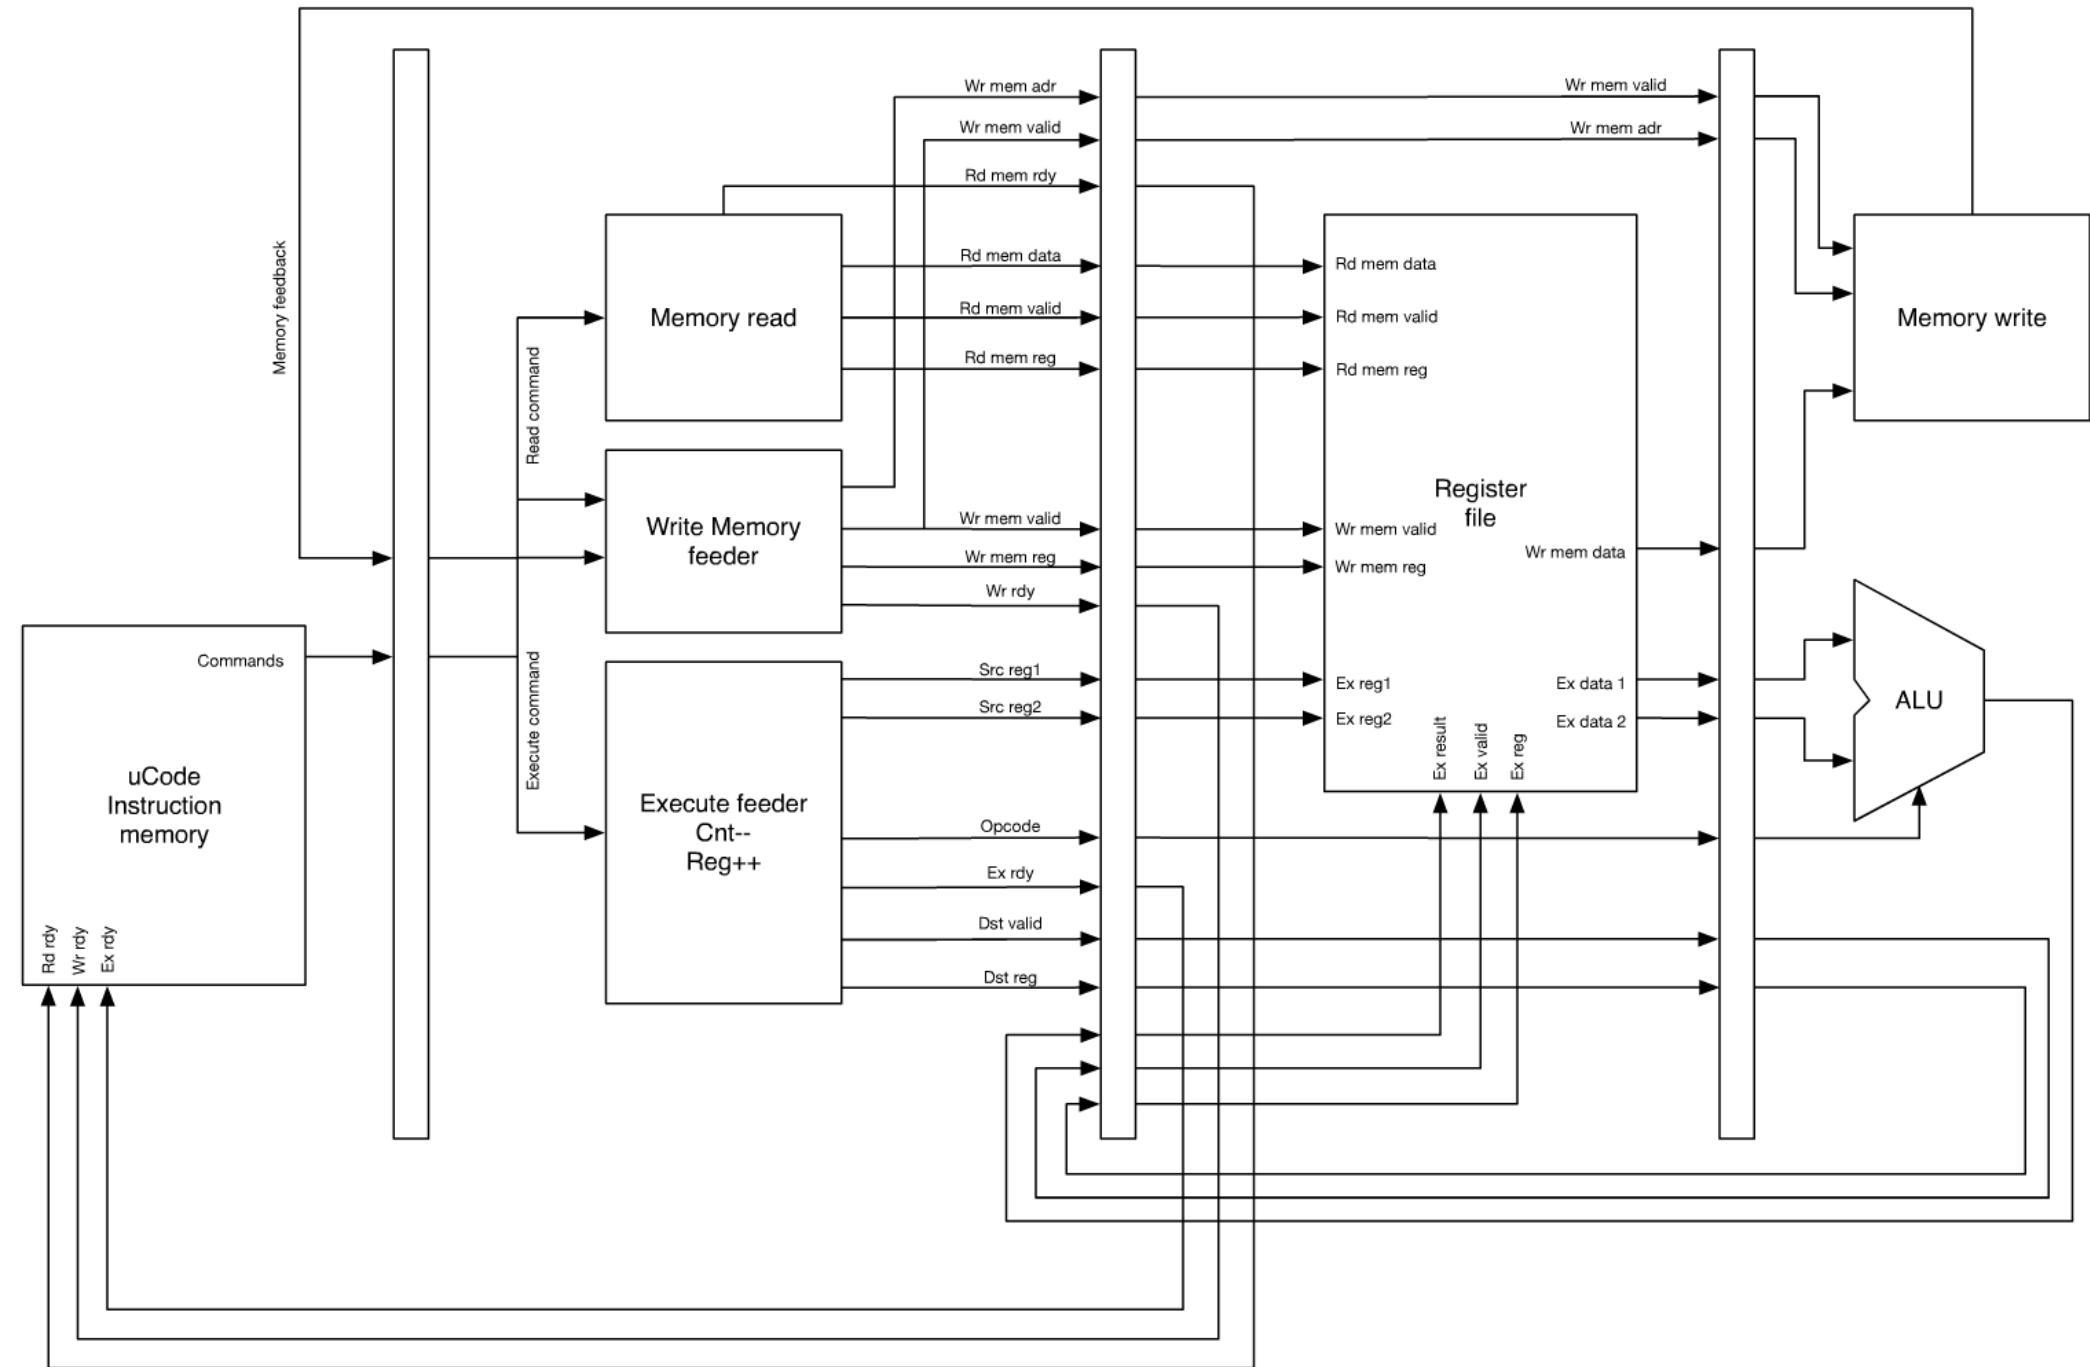

It is a perfect fit for the Bohrium libraries, and essentially a processor designed for the programming model.

# Why FPGA ?

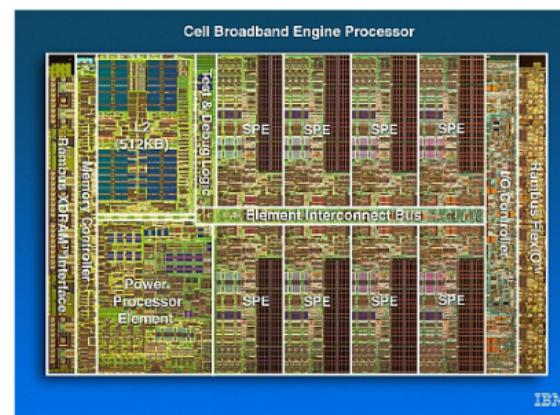

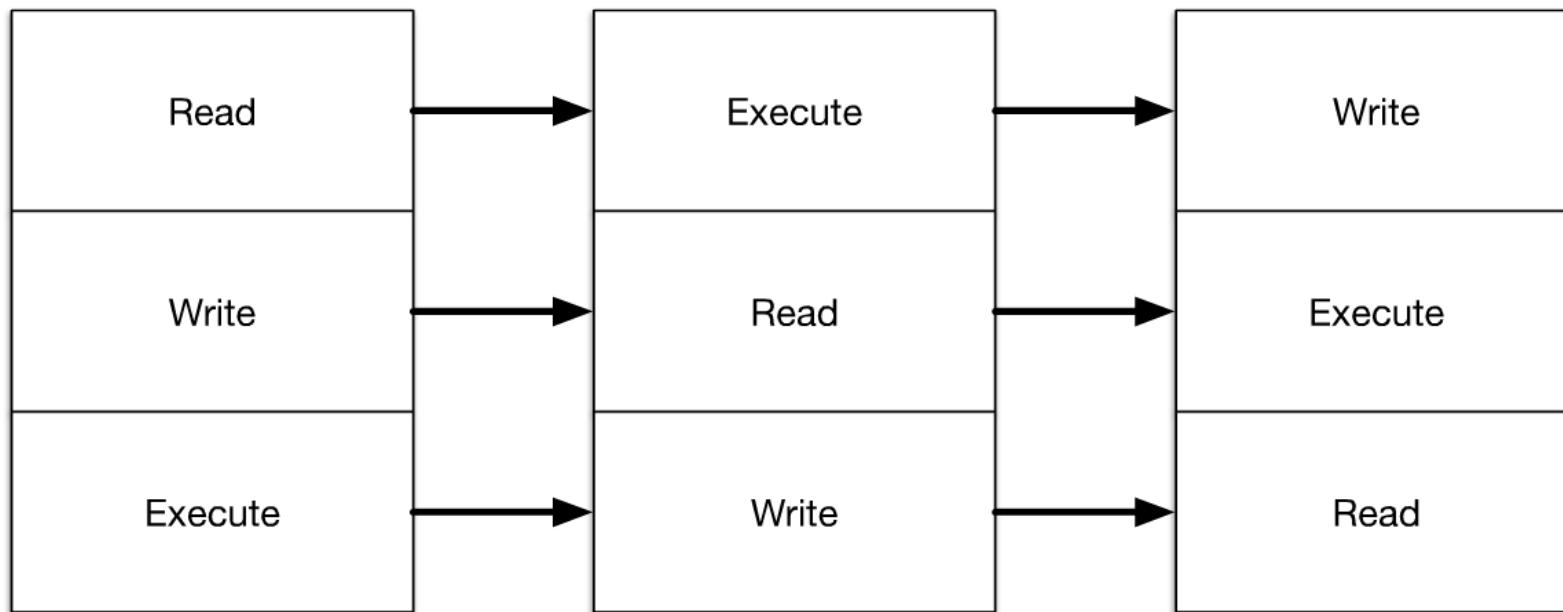

# Register file shuffle - 3-state execution

## Triple buffering

# Micro-code design

Each microcode can express 3 distinct operations:

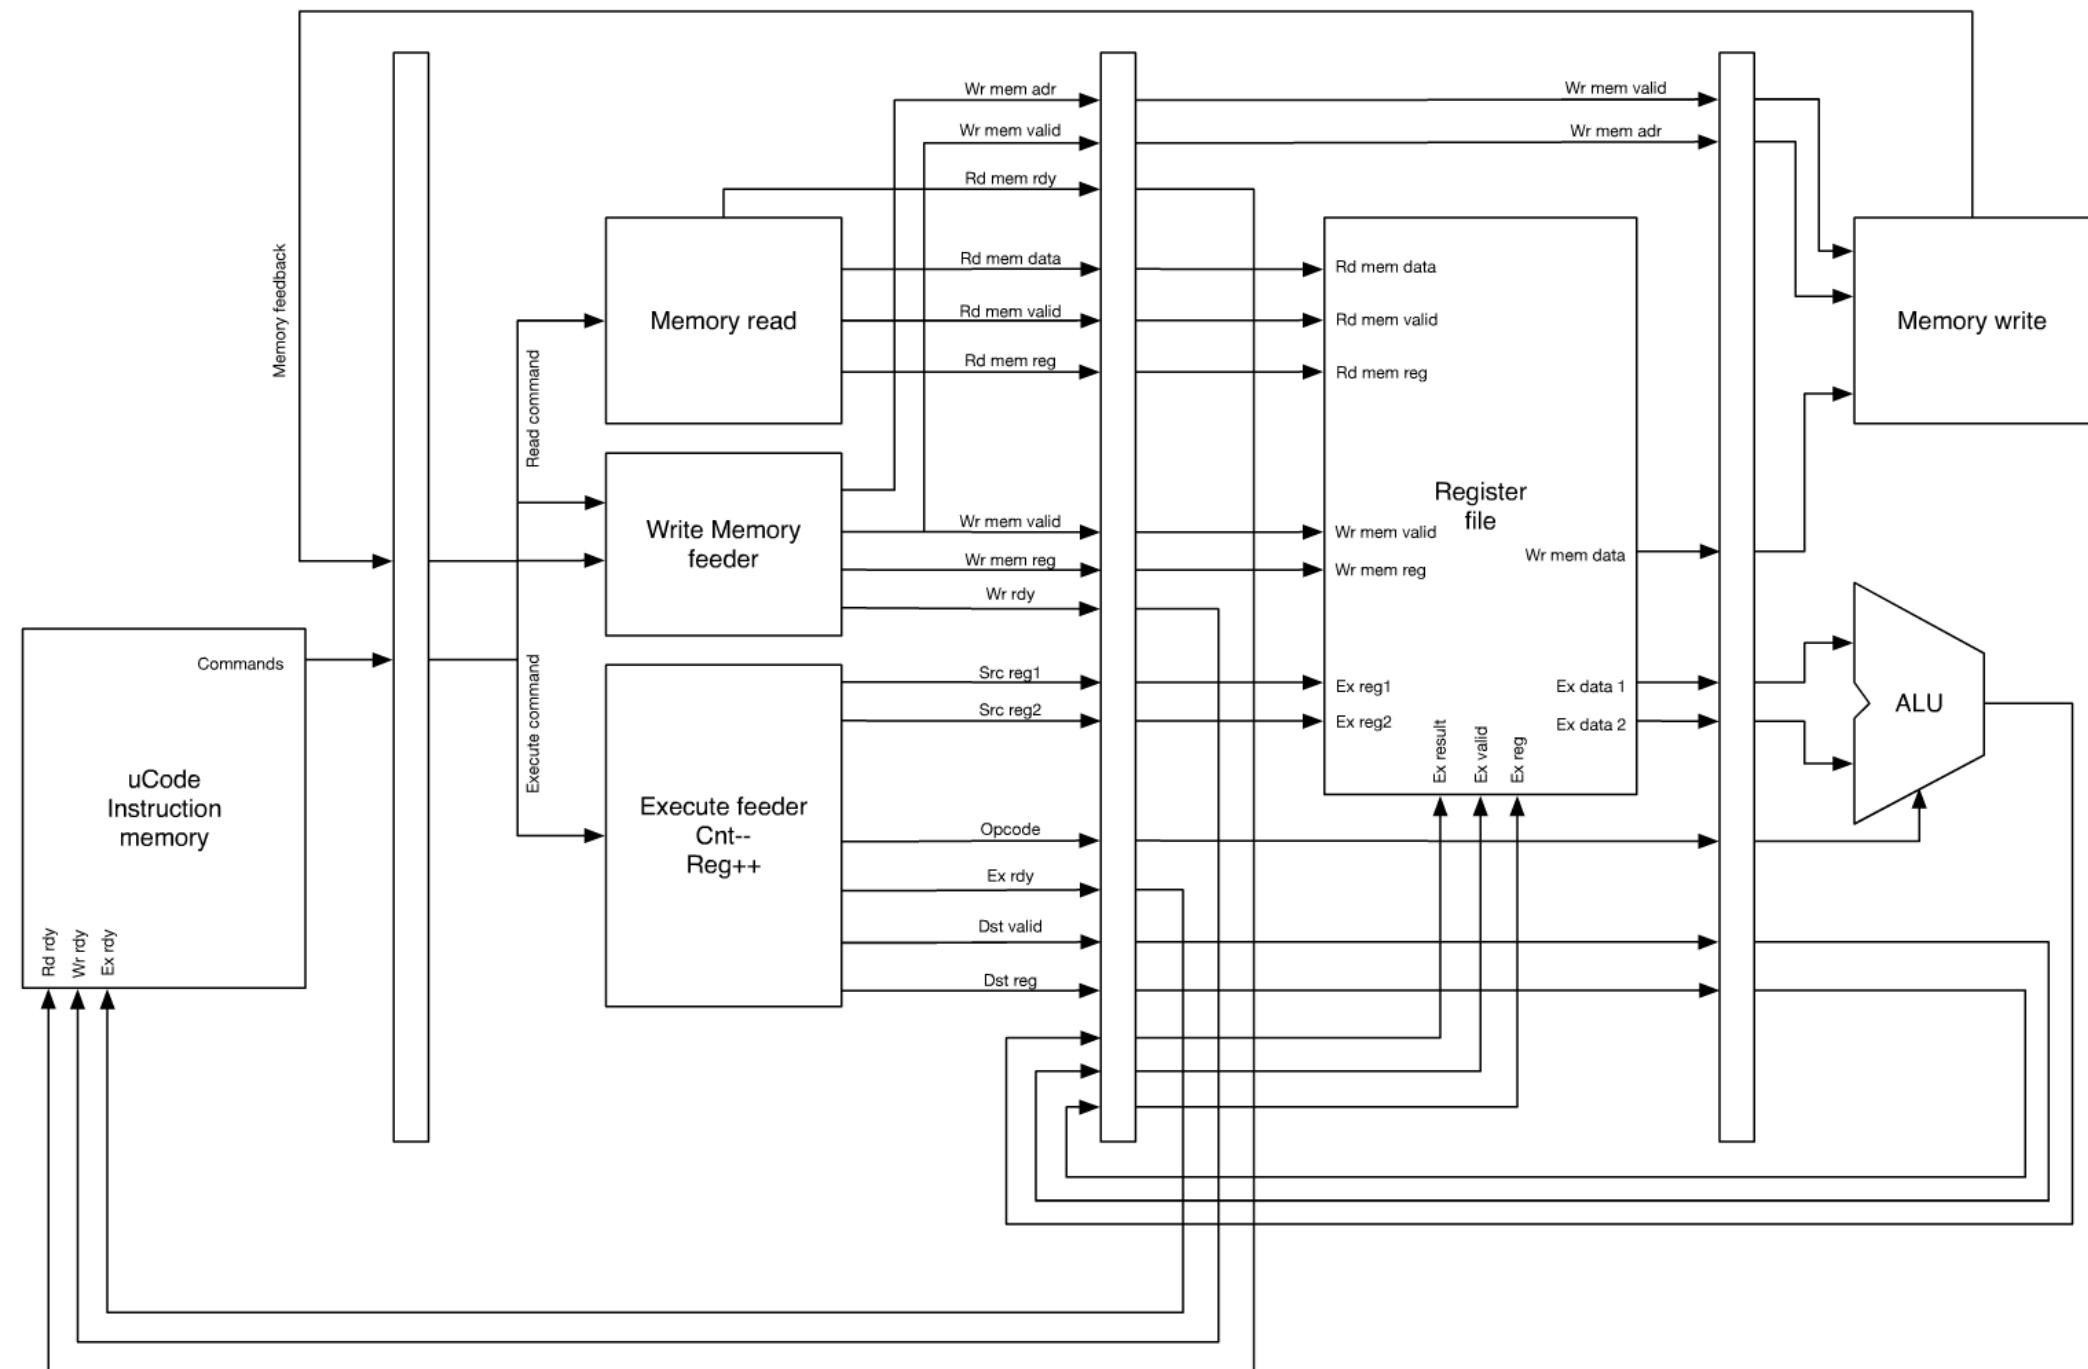

- Vectorized memory read
- Vectorized memory write
- Vectorized execute

Each microcode can depend on previous instructions

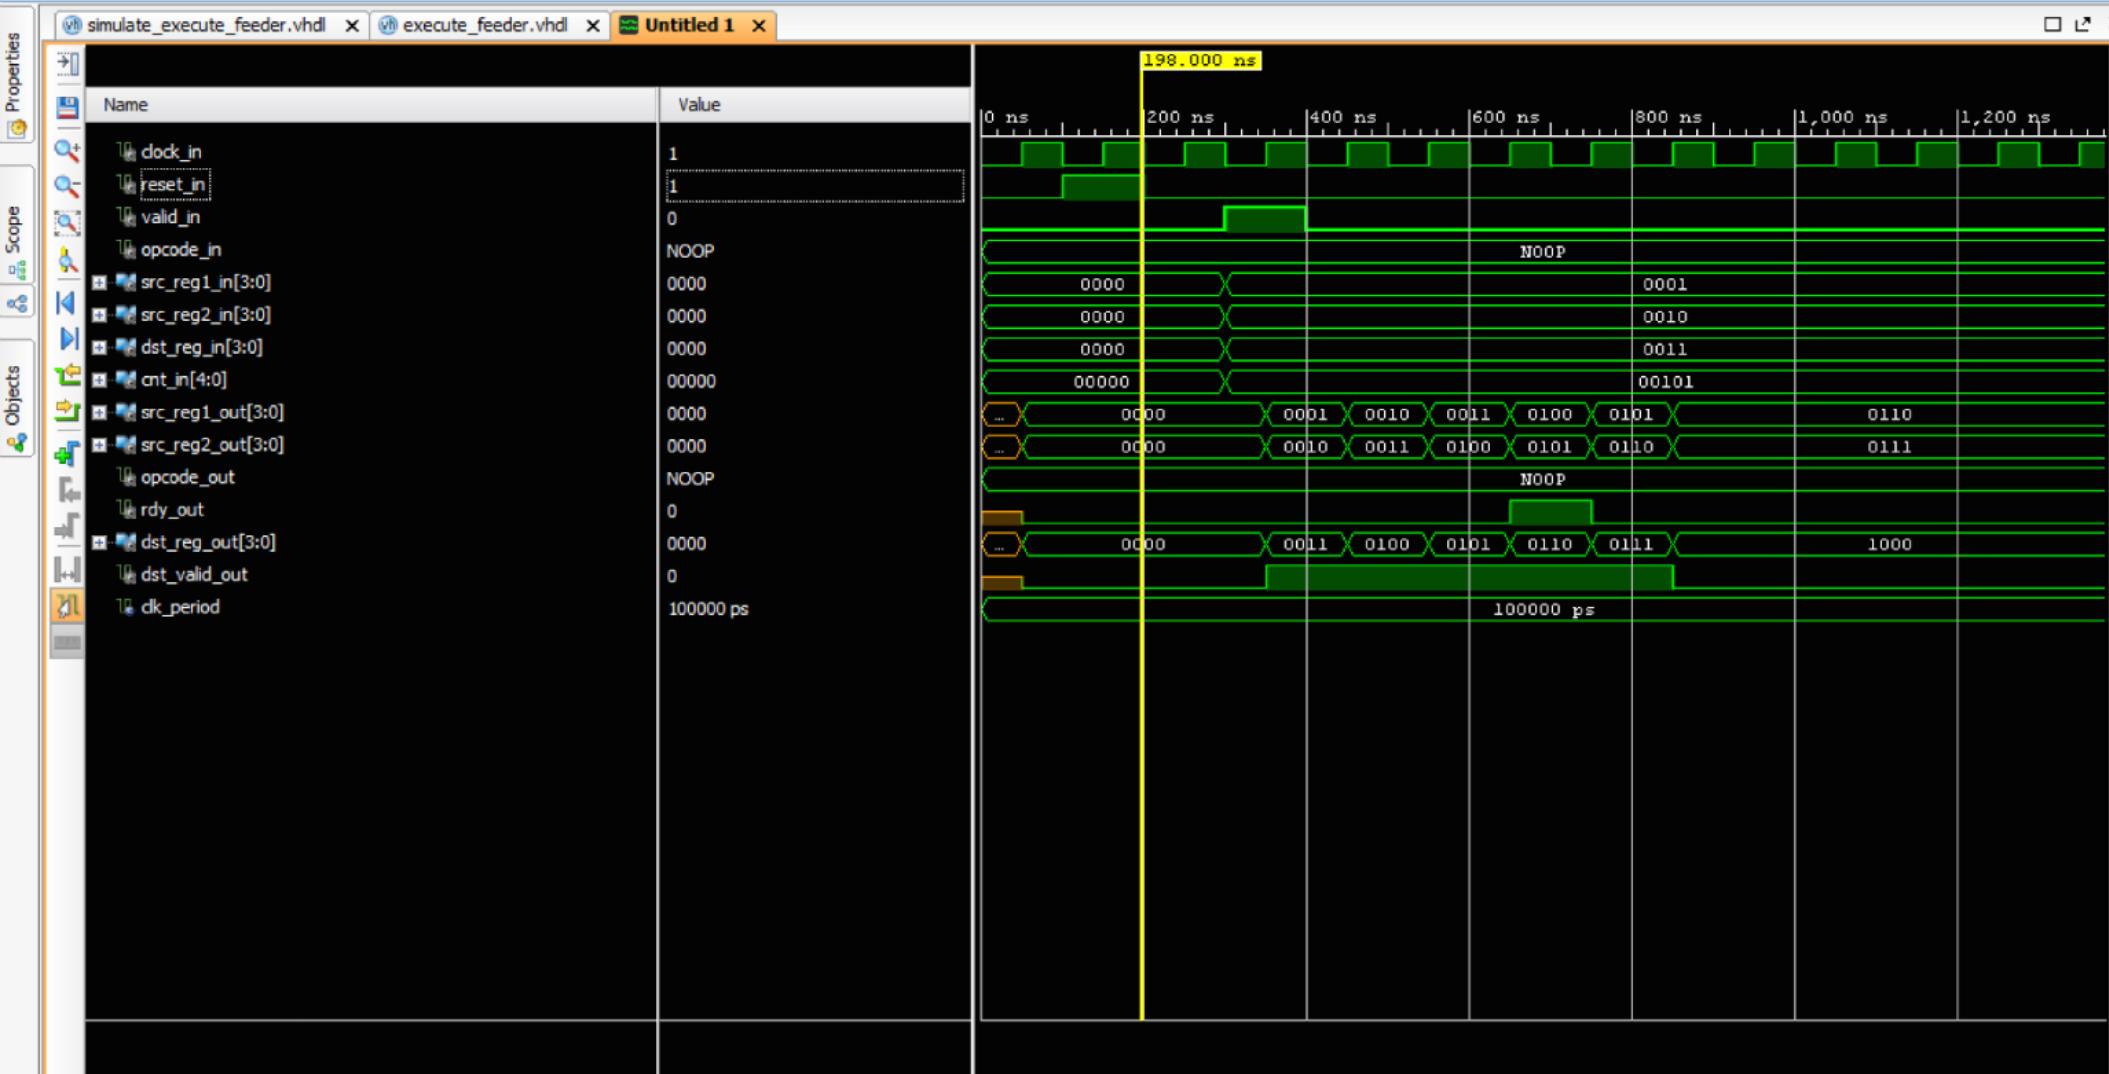

- For read
- For write
- For execute

The micro-code design places a large burden on the programmer and is not suited for writing conventional programs

But it is a perfect fit for the Bohrium bytecode, and essentially a processor designed for the programming model

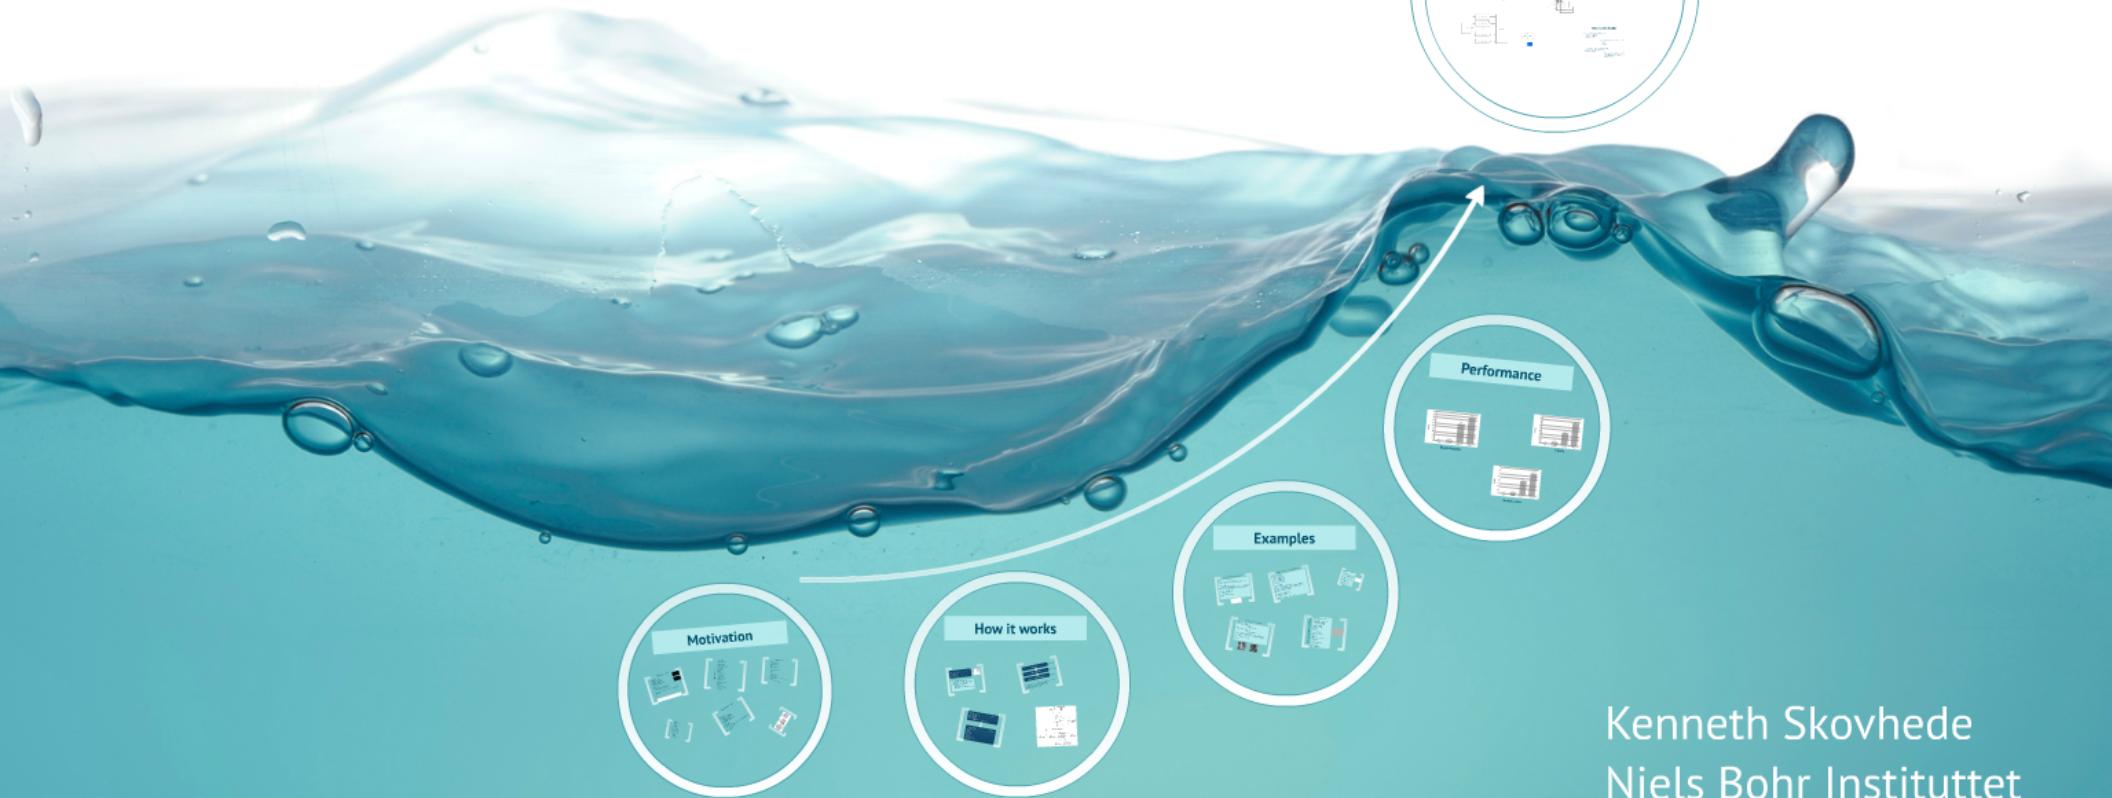

## Behavioral Simulation - Functional - sim\_1 - simulate\_execute\_feeder

# Bohrium

Bridging high performance and high productivity
